ABSTRACT

The theory of finite Fourier transforms is developed from the definitions of infinite transforms and applied to the computation of convolutions, correlations, and power spectra. Detailed procedures for these computations are given, including listings and writeups of FORTRAN subroutines.

1. <u>INTRODUCTION</u>

For the past several months, E. A. Flinn, J. F. Claerbout, and I have been examining some practical and computational aspects of the theory of Fourier transforms. These efforts have resulted in a set of programs for performing operations on time series based on the Cooley-Tukey (References 1,2) hyper-rapid Fourier transform method. Using this method, computations on seismic array data such as the calculation of convolutions, correlations, spectra, and digital filters have been speeded up by factors of three or four and sometimes even ten. The purpose of this report is to communicate these results in a straightforward manner and to offer some motivation for their derivation as well as for future efforts in this area. Writeups and listings of the programs discussed here are included as appendices to this report.

2. THE FINITE AND DISCRETE FOURIER TRANSFORMS

In the case of continuous data of infinite length, the Fourier transform pair is usually written as:

$$A(w) = (2\pi)^{-\frac{1}{2}} \int_{-\infty}^{\infty} f(t)e^{-i\omega t}dt$$

 $f(t) = (2\pi)^{-\frac{1}{2}} \int_{-\infty}^{\infty} A(w)e^{i\omega t}dw$ (1)

The first of these, going from time to frequency, is referred

to as the direct transform and the other as the inverse transform. Sometimes the direct transform is written with a factor of 1 in front of the integral and the inverse with a factor of $1/2\pi$. These are, of course, equivalent to the above definition. Quantities of interest, such as spectra, etc., involve magnitudes or squares of one transform and the factor must be inserted or taken out, depending on which definition is used, to preserve the proper dimensions.

Two drawbacks of these definitions for digital computations are apparent: First, the integrals must be approximated by sums in the digital computer, which implies that both transforms involve sampled variables. Second, the infinite limits on the sums are impossible in practice. Clearly, these sums must be truncated, as they do not in general converge over a finite interval. As a result Fourier transforms as such are never really computed by a digital computer. Instead, the complex samples of a direct transform are approximated by the cosine and sine coefficients of Fourier series representation of the input data. The definitions for these are:

if
$$x(t) = \sum_{n=0}^{\infty} \left[a_n \cos (\pi n t/T) + b_n \sin (\pi n t/T) \right],$$
 (2)

then
$$a_0 = \frac{1}{T} \int_0^T x(t) dt$$
 $b_0 = 0$ (3)

$$a_n = \frac{2}{T} \int_0^T x(t) \cos(\pi n t/T) dt$$

$$b_n = \frac{2}{T} \int_0^T x(t) \sin (\pi n t/T) dt$$

If N samples of the data are taken at equally spaced intervals $\Delta t = T/N$, the integrals (3) becomes sums and the frequency sum in (2) goes from DC to the folding frequency, i.e., k=0 to N/2T. The equations are then written as:

$$x(j) = \sum_{k=0}^{N/2} \left[a_k \cos (2\pi j k/N) + b_k \sin (2\pi j k/N) \right]$$

$$a_0 = \frac{1}{N} \sum_{j=0}^{N-1} x(j)$$

$$b_0 = 0$$

$$j = 0$$
(4)

$$a_k = \frac{2}{N} \sum_{j=0}^{N-1} x(j) \cos(2\pi j k/N)$$
 $b_k = \frac{2}{N} \sum_{j=0}^{N-1} x(j) \sin(2\pi j k/N), \quad (5)$

where t has been replaced by $j\Delta t$. By now defining:

$$A(k) = \frac{1}{2} (a_k - i b_k) , \quad A(0) = a_0$$
 (6)

and realizing that a real time series contains only real points, we can write (4) as:

$$N/2$$

$$x(j) = \sum_{k=0}^{N/2} A(k) \exp (2\pi i j k/N)$$
(7)

A great deal of symmetry between the two transforms can be

preserved if the sum in (7) is summed up to N-1. Redundant points in the spectrum are included (since the transforms are periodic) but the computational procedures are simplified. It is also convenient to split the factor of 1/N appearing in (5) into two factors of $1/\sqrt{N}$, one in front of each transform. By defining a complex number:

$$w = \exp (2\pi i/N) , \qquad (8)$$

the two transforms can now be written as

$$A(k) = \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} f(j) w^{-jk}$$
(9)

$$f(j) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} A(k) w^{jk}$$
 (10)

It can be shown that the set of direct Fourier transform points, between DC and the folding frequency, contains the same amount of information as the real data series: The transform includes N/2 distinct points, which with the DC term makes a total of N/2 + 1 complex points. Equation (9) shows that both the DC and the folding frequency point are purely real; thus, the Fourier transform contains (N/2-1)*2+2*1 numbers. This is exactly the same amount of information contained in the real time series. It also suggests that the existence of one transform should imply the existence of the other.

If there are N/2+1 non-redundant points in the direct transform, then the sampling interval in frequency must be

(N/2T)/(N/2) = 1/T . Thus, the product of the time and frequency variables is:

$$i\omega t = i(2\pi k \cdot \frac{1}{T}) \quad (j\frac{T}{N}) = \frac{2\pi i}{N} \quad jk$$
 (11)

This equation relates the arguments in the two exponentials, one in the continuous transform and the other in the finite transform (Equations 1, 9, and 10).

3. TWO- AND THREE-DIMENSIONAL FOURIER TRANSFORMS

Two- and three-dimensional direct Fourier transforms are seen to be

$$A(k_{1},k_{2}) = \frac{1}{\sqrt{N_{1}N_{2}}} \sum_{j_{1}=0}^{N_{1}-1} \sum_{j_{2}=0}^{N_{2}-1} x(j_{1},j_{2}) w_{1}^{-j_{1}k_{1}} w_{2}^{-j_{2}k_{2}}$$
(12)

and

$$A(k_{1},k_{2},k_{3}) = \frac{1}{\sqrt{N_{1}N_{2}N_{3}}} \sum_{j_{1}=0}^{N_{1}-1} \sum_{j_{2}=0}^{N_{2}-1} \sum_{j_{3}=0}^{N_{3}-1} x(j_{1},j_{2},j_{3}) w_{1}^{-j_{1}k_{1}}.$$

$$w_{2}^{-j_{2}k_{2}} w_{3}^{-j_{3}k_{3}} (13)$$

We can break up Equation (12) as follows:

$$A(k_1,k_2) = \sqrt{\frac{1}{N_2}} \sum_{j_2=0}^{N_2-1} B(k_1,j_2) w_2^{-j_2k_2}$$
(14)

This calculation requires \mathbf{N}_1 one-dimensional transforms; we have defined

$$B(k_{1},j_{2}) = \frac{1}{\sqrt{N_{1}}} \sum_{j_{1}=0}^{N_{1}-1} x(j_{1},j_{2}) w_{1}^{-j_{1}k_{1}}$$
(15)

which requires N $_2$ one-dimensional transforms. Thus, N $_1$ + N $_2$ one-dimensional transforms are required to compute the single two-dimensional transform.

We can break up Equation (13) as follows:

$$A(k_1, k_2, k_3) = \frac{1}{\sqrt{N_3}} \sum_{j_3=0}^{N_3-1} C(k_1, k_2, j_3) w_3^{-j_3 k_3}$$
 (16)

which requires N_1N_2 one-dimensional transforms; we have defined

$$c(k_{1},k_{2},j_{3}) = \frac{1}{\sqrt{N_{1}N_{2}}} \sum_{j_{1}=0}^{N_{1}-1} \sum_{j_{2}=0}^{N_{2}-1} x(j_{1},j_{2},j_{3}) w_{1}^{-j_{1}k_{1}} w_{2}^{-j_{2}k_{2}}$$
(17)

which requires N $_3$ two-dimensional transforms. Thus, N $_1$ N $_2$ one-dimensional transforms and N $_3$ two-dimensional transforms are needed to compute the single three-dimensional transform.

4. ALGEBRAIC DISCUSSION

Equations (9) and (10) suggest a more elegant and compact way to write the two transfor s. We define the vector \mathbf{A} as the transform with elements $(\mathbf{A})_k = \mathbf{A}(k)$, and define the vector \mathbf{F} as the time series with elements $(\mathbf{F})_j = \mathbf{F}(j)$. The process of transforming is seen to be equivalent to matrix multiplication by a matrix \mathbf{W} whose elements are $(\mathbf{W})_{jk} = \mathbf{W}^{jk}$

$$A = W^{\dagger} f \tag{18}$$

and
$$f = WA$$
, (19)

where the dagger indicates Hermitian conjugation. Substituting (19) into (18) gives the following important identity:

$$WW^{+} = W^{+}W = I \qquad (20)$$

This is the definition of unitarity for the transformation W It is a generalization of orthogonality for complex matrices and assures Parseval's theorem:

$$\mathbf{A}^{+}\mathbf{A} = \mathbf{f}^{+}\mathbf{f} \qquad (21)$$

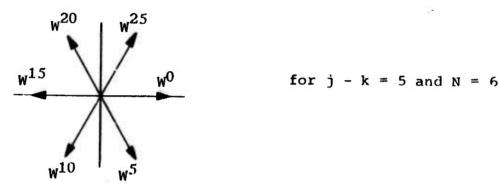

W preserves "length" between the two domains. The identity is actually proved by writing out the terms in the product:

$$\frac{1}{N} \sum_{m=0}^{N-1} \left[\exp(2\pi i/N) \right]^{jm} \left[\exp(-2\pi i/N) \right]^{mk} = \delta_k^j$$

or

$$\frac{1}{N} \sum_{m=0}^{N-1} w^{m(j-k)} = \delta_k^j$$
 (22)

This last important relation is seen to be true by the use of a phase diagram:

The Cooley-Tukey method factors the W matrix, if its order is a power of two, into L+1 sparse matrices, where L is the power of two:

$$\mathbf{W} = \mathbf{S}_{\mathbf{L}} \mathbf{S}_{\mathbf{L}-1} \dots \mathbf{S}_{1} \mathbf{S}_{0}$$

Multiplying L+1 times by these sparse matrices can in some cases reduce the computing time by many tens of times. This factorization is proved by Good (3) and organized for computation by Rader (4).

For the case N = 8 the W matrix is:

$$W = \frac{1}{\sqrt{8}} \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & w^{1} & w^{2} & w^{3} & w^{4} & w^{5} & w^{6} & w^{7} \\ 1 & w^{2} & w^{4} & w^{6} & w^{8} & w^{10} & w^{12} & w^{14} \\ 1 & w^{3} & w^{6} & w^{9} & w^{12} & w^{15} & w^{18} & w^{21} \\ 1 & w^{4} & w^{8} & w^{12} & w^{16} & w^{20} & w^{24} & w^{28} \\ 1 & w^{5} & w^{10} & w^{15} & w^{20} & w^{25} & w^{30} & w^{35} \\ 1 & w^{6} & w^{12} & w^{18} & w^{24} & w^{30} & w^{36} & w^{42} \\ 1 & w^{7} & w^{14} & w^{21} & w^{28} & w^{35} & w^{42} & w^{49} \end{bmatrix}$$

$$(22.1)$$

The L + 1 = 4 transformations are graphically illustrated by the following diagram in Rader's notation (Reference 4):

INDEX	BINARY	ARRAY	s ₀	s ₁	s ₂	s ₃	RE- VERSED	INDEX

Each solid line represents a multiplication by w to the

power indicated in the circle, and each dotted line represents a simple addition into that element of the array. No additional storage is used by this process. The results of each transformation are stored on top of the original data, and the last transformation, which is a simple interchange, gives the desired Fourier transform. Note also that the succession of numbers in the circles is the bit-reversed representation of the sequence of indices in order. They can be stored in a table or generated successively by a reverse-add procedure. For reasons of space and simplicity, we have chosen the latter route.

The S matrices are:

$$s_0 = \frac{1}{\sqrt{2}} \quad \begin{cases} 1 & 0 & 0 & 0 & w^0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & w^0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & w^0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & w^0 \\ 1 & 0 & 0 & 0 & w^4 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & w^4 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & w^4 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & w^4 \end{cases}$$

5. HIGH-SPEED CORRELATIONS AND CONVOLUTIONS

By computing Fourier transforms with this finite Fourier series-like method an important condition is put on the time series. As in regular Fourier series the input is assumed to be periodic with period T and the integrals or sums are computed over a single period. There is also the effect of cutting off the spectrum at the folding frequency. Sines and cosines of finite wavelength will repeat again outside the region of interest. This fact in itself is not bothersome but becomes a serious complication in the computation of convolutions and correlations. Convolutions and correlations as usually computed assume the time series to be zero outside the region of interest. Therefore, the integrals or sums in computing them are summed out only over the non-zero terms. When multiplying together two finite Fourier transforms (or the complex conjugate of one times the other) the periodicity of the time series means that elements which have been shifted past the end of a period reappear at the beginning. process is called circular convolution or correlation and its effects are unavoidable when straightforwardly computing lagged products with finite Fourier transforms. This is illustrated below:

$$X_1 = (3, 0, -1, 2)$$
 $X_2 = (-2, 2, -1, 3)$
 $R_{12}^C = (1, -1, 3, 5)$ for 100% positive lags;
 $= (1, 5, 3, -1)$ for 100% negative lags.

Circular convolution is therefore written:

$$R_{ij}^{C}(t) = \sum_{\tau=0}^{T-1} x_{i}(\tau) x_{j}(t + \tau)$$
 (23)

where $x_m(t + T) = x_m(t)$ for all m.

The proof that this kind of correlation is equal to the transform of the absolute product of the two finite transforms follows below:

$$\sum_{t=0}^{T-1} R_{ij}^{c}(t) w^{-tk} = \sum_{t=0}^{T-1} \sum_{\tau=0}^{T-1} x_{i}(\tau) x_{j}(t+\tau) w^{-tk}$$
(24)

$$T-1 \quad T-1+\tau$$
= $\sum_{\tau=0}^{\infty} \sum_{q=\tau}^{\infty} x_{i}(\tau) x_{j}(q) w^{-(q-\tau)k}$ $q = t + \tau$

$$T-1 = \sum_{\tau=0}^{T-1} x_{i}(\tau) w^{\tau k} \sum_{q=0}^{T-1} x_{j}(q) w^{-qk}$$

$$= A_{j}^{*}(k) A_{j}(k)$$

On the other hand the transient correlation for positive lags is defined by the following:

$$R_{1j}^{7'}(t) = \sum_{\tau=0}^{T-1-t} x_{i}(\tau) x_{j}(t + \tau)$$
 (25)

where the upper limit on the sum simulates the desired zeros in the time series outside the region of interest. This is illustrated below:

$$X_1 = (3, 0, -1, 2)$$

$$X_2 = (-2, 2, -1, 3)$$

$$R_{12}^{T'} = (1, 3, -3, 9)$$
 for 100% positive lags;
$$= (1, -4, 6, -4)$$
 for 100% negative lags.

The finite Fourier transform of this R^T is thus not the product of the two individual transforms. However, by filling zeros into the second half of each data series and computing their transforms out to twice their actual length, a good estimate of the spectrum may be obtained. In addition, the negative lags in the correlation appear, thus giving a more mathematically satisfying result. This is illustrated below:

$$x_1 = (3, 0, -1, 2, 0, 0, 0, 0)$$

 $x_2 = (-2, 2, -1, 3, 0, 0, 0, 0)$
 $R_{12}^C = (1, 3, -3, 9, 0, -4, 6, -4)$ for 100% positive lags.

The two modified transforms thus are:

$$F_{i}(k) = \sum_{t=0}^{2T-1} x_{i}(t) w^{-tk}$$
 $x_{i}(t) = 0, T \le t \le 2T-1$

$$S_{ij}(k) = F_{i}(k)^{*} F_{j}(k) = \sum_{t=0}^{2T-1} x_{i}(t) w^{tk} \sum_{\tau=0}^{2T-1} x_{j}(\tau) w^{-\tau k}$$

$$R_{ij}^{?}(s) = \sum_{k=0}^{2T-1} F_{i}(k)^{*} F_{j}(k) w^{ks} =$$

$$\sum_{t=0}^{2T-1} \sum_{\tau=0}^{2T-1} x_{i}(t) x_{j}(\tau) \sum_{k=0}^{2T-1} w^{k(t+s-\tau)} .$$
(26)

Now from (22) the last sum becomes a Kronecker delta function and the other sum is collapsed to give:

$$R_{ij}^{?}(s) = \sum_{t=0}^{2T-1} x_{i}(t) x_{j}(t+s) = R_{ij}^{T}(s)$$

The last equality following from the original assumption that $x_i(t) = 0$, $T \le t \le 2T-1$. Transient correlations for 100% lags are therefore computed by forming the absolute product of two transforms, each computed out to twice the length of the original data series with zeros filled into the second halves.

Non-circular or transient convolutions are computed in much the same way, except that the transforms have to be computed out to a length equal to the sum of the lengths of the time series and the filter, with the appropriate number of zeros filled into each. The convolution theorem is proved in the same fashion.

$$T+S-1$$

$$A(k) = \sum_{\tau=0}^{\infty} a(\tau) w^{-\tau k} \qquad a(\tau) = 0 , \quad S \leq \tau \leq T + S - 1$$

$$\overline{X}(k) = \sum_{t=0}^{T+S-1} x(t) w^{-tk} \qquad x(t) = 0 \qquad T \le t \le T+S-1$$

$$\sum_{k=0}^{T+S-1} A(k) X(k) w^{ku} = \sum_{\tau=0}^{T+S-1} \sum_{t=0}^{T+S-1} a(\tau) x(t) \sum_{k=0}^{T+S-1} w^{k(u-\tau-t)}$$

T+S-1
$$\sum_{k=0}^{T+S-1} A(k) x(k) w^{ku} = \sum_{\tau=0}^{T+S-1} a(t) x(u-t) = y(u)$$
(27)

Where y(u) is now the "filtered" output of the filter a acting on X. Convolutions are therefore computed by forming the product of the two transforms, each computed out to a length equal to their sum with zeros filled into the extra lengths. Detailed procedures for these computations are listed in Appendix A.

APPENDIX A - PROCEDURES

FINITE FOURIER TRANSFORM THEORY AND ITS APPLICATION TO THE COMPUTATION OF CONVOLUTIONS, CORRELATIONS, AND SPECTRA

DIMENSION X(2*LX+2), CX(LX+1)

EQUIVALENCE (X,CX)

TYPE COMPLEX CX, CONJG

LX = 2**N

- Erase 2*LX+2 points in X: the extra complex point is needed by COOLER to return the point at the folding frequency.
- 2) Read the data channel into X(1) through X(LX).
- 3) CALL COOLER(N+1,CX). The Fourier transform of X and the necessary zeros on the end of the data is now stored in CX, LX+1 complex points long, representing frequencies between DC and the folding frequency.
- 4) Go through the LX+1 complex points in CX, and:

CX(I) = [CONJG(CX(I))*CX(I)]/LX

that is,

 $Re[CX(I)] = (Re[CX(I)]^{2} + Im[CX(I)]^{2})/LX$ Im[CX(I)] = 0.0

The auto-spectrum is the real part of CX, purely real and LX+1 points in length.

5) To get the auto-correlation, fill in the other LX-l complex points in CX as required by COOL for inverse transforms, and call COOL:

DO 1 I = 1, LX-1

 $1 \quad CX(LX+1+I) = CX(LX-I+1)$

CALL COOL(N+1,CX,+1.0)

The auto-correlation is in the real part of CX, purely real and 2*LX points in length.

NOTE: CX must be dimensioned 2*LX if the auto-correlation is to be computed.

PROCEDURE FOR CALCULATING A CROSS SPECTRUM AND A CROSS-CORRELATION

DIMENSION X(2*LX+2), CX(LX+1), Y(2*LX+2), CY(LX+1)

EQUIVALENCE (X,CX), (Y,CY)

TYPE COMPLEX CX,CY

LX = 2**N

- 1) Erase 2*LX+2 points and both X and Y.
- 2! Read channel 1 into X and channel 2 into Y.
- 3) CALL COOLER(N+1,X)
 CALL COOLER(N+1,Y)
- 4) Go through the LX+1 complex points and overlay CX (or CY) with:

CX(I) = [CONJG(CX(I))*CY(I)]/LX

that is.

Re[CX(I)] = (Re[CX(I)]*Re(CY(I)]+Im[CX(I)]*Im[CY(I)])/LX Im[CX(I)] = (Re[CX(I)]*Im[CY(I)]-Im[CX(I)]*Re[CY(I)])/LX

The cross-spectrum between channel 1 and channel 2 (which is the complex conjugate of the cross-spectrum between channel 2 and channel 1) is now in CX, LX+1 points in length. The co-spectrum is in the real part of CX and the quad-spectrum is in the imaginary part of CX.

5) To get the cross-correlation, fill in the other LX-l points in CX and call COOL:

DO 1 I = 1,LX-1

1 CX(LX+I+1) = CONJG(CX(LX-I+1))

CALL COOL(N+1,CX,+1.0)

The cross-correlation is in the real part of CX, purely real and 2*LX points in length.

NOTE: CX must be dimensioned 2*LX if the cross-correlation is to be calculated.

PROCEDURE FOR CALCULATING THE CONVOLUTION OF TWO SERIES

DIMENSION x(L+2), $cx(\frac{1}{2}L+1)$, F(L+2), $cF(\frac{1}{2}L+1)$ EQUIVALENCE (x,cx), (F,cF)TYPE COMPLEX cx,cF, conjgL = 2*+n

L here is the next power of 2 larger than LX+LF, the combined length of the data and the filter.

- 1) Erase L+2 points in X and F.
- 2) Read the data into X(1) through X(LX) and the filter impulse response into F(1) through F(LF).
- 3) CALL COOLER(N,CX)
 CALL COOLER(N,CF)
- 4) Go through the 1241 complex points in CX, and:

CX(I) = fCX(I)*CF(I) I/LX

that is,

 $\begin{aligned} & \operatorname{Re}[\operatorname{CX}(I)] = & \left(\operatorname{Re}[\operatorname{CX}(I)] + \operatorname{Re}[\operatorname{CF}(I)] - \operatorname{Im}[\operatorname{CX}(I)] + \operatorname{Im}[\operatorname{CF}(I)] \right) / \operatorname{LX} \\ & \operatorname{Im}[\operatorname{CX}(I)] = & \left(\operatorname{Re}[\operatorname{CX}(I)] + \operatorname{Im}[\operatorname{CF}(I)] + \operatorname{Re}[\operatorname{CF}(I)] + \operatorname{Im}[\operatorname{CX}(I)] \right) / \operatorname{LX} \end{aligned}$ The Fourier + cansform of X convolved with F is now in CX.

5) Fill in the rest of the points in CX as needed by COOL, and transform back. Note again that if the actual convolution is desired instead of the Fourier transform, CX must be dimensioned L.

DO 1 I = 1, L-1

The convolution of X with F is now in the real part of CX, purely real, and LX+LF-1 points in length.

APPENDIX B - PROGRAM LISTINGS

FINITE FOURIER TRANSFORM THEORY AND ITS APPLICATION TO THE COMPUTATION OF CONVOLUTIONS, CORRELATIONS, AND SPECTRA

C C

HYPER-RAPID FUURIER THANSFUHM USING COOLEY-TUKEY ALGORITHM

SEISMIC DATA LABORATORY, ALEXANDRIA, VA. PROGRAMMED 26 FEBRUARY 1966 RY J. F. CLAEREOUT (MIT), D. W. MCCOMAN. E. A. FLINN, AND JI GIBSON (TELEDYNE)

X IS A COMPLEX ARRAY USED FOR THE DATA SERIES AND THE

TRANSFORM - THE NUMBER OF ELEMENTS OF X IS L = 2 . SIGN = -1.0 FUR DIRECT FOURIER TRANSFORM AND +1.0 FOR INVERSE FOURIER THANSFORM (BUT SEE BELCW FOR ARRANGEMENT OF DATA FOR INVERSE TRANSFORM).

FOR DIRECT THANSFORM, ON INPUT THE REAL PART OF X GONTAINS THE DATA SERIES AND THE IMAGINARY PART OF X IS ZERO. ON RETURN. THE FUURIER CUSINE SERIES EXPANSION OF THE DATA IS IN THE REAL PART OF X, AND THE FOURIER SINE SERIES EXPANSION IS IN THE

IMAGINARY PART OF X. EACH CONTAINS ONLY 2 + 1 NONREDUNDANT POINTS. THE COSINE EXPANSION IS SYMMETRIC ABOUT POINT NUMBER

N-1 + 1 AND THE SINE TRANSFORM IS ANTISYMMETRIC ABOUT THIS POINT.

FOR EXAMPLE - N = 3 AND DATA = (0.,1.,0;,0.,0.,0.,0.,0.,0.), THEN REAL PART OF X = (J.,1.,0.,0.,0.,0.,0.,0.) AND IMAGINARY PART OF X = (0,,0,,0,,0,,0,,0,,0,,0,) ON INPUT. ON RETURN, REAL PART OF X = (1.000,.7071,0,,-.7071,-1.000, -.7071,6.,+.7071: AND IMAGINARY PART OF X = (0.,-.3071, -1.000,-.7071,0.,.7071,1.000,.7071). POINT NUMBER 1 CORRESPONDS TO ZERO FREQUENCY, POINT NUMBER 5 CORRESPONDS TO PI, THE FOLDING PREQUENCY,

TO DO AN INVERSE TRANSFORM, THE COSINE AND SINE SERIES MUST BE

2 FOLDED OVER ABOUT POINT NUMBER + 1 BEFORE CALLING SUBROUTINE FTPACK CAN BE USED TO DO COOL WITH SIGN = +1.0. THIS FOR YOU, CONVERTING AMPLITUDE AND PHASE BACK TO SINE AND CUSING IF NEED BE.

WHICH COOL DGES NOT APPLY. THERE IS A SUALE FACTOR OF 2

THE USER CAN APPLY THE SCALE FACTOR EITHER TO THE DIRECT OR TO

THE INVERSE THANSFORM, OR APPLY A SCALE FACTOR OF 2 TO

C

FINITE FOURIER TRANSFORM THEORY AND ITS APPLICATION TO THE COMPUTATION OF CONVOLUTIONS, CORRELATIONS, AND SPECTRA

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. IDENTIFICATION

<u>Title</u>: Hyper-Rapid Specialized Cooley-Tukey Fourier Trans-

form (direct only)

COOP Identification: G612-COOL

Category: Fourier Transform

Programers: J. F. Claerbout, D. W. McCowan, J. L. Gibson,

and E. A. Flinn

Pate: 26 February 1966

B. PURPOSE

To compute the Fourier series expansion of a real-or complex-valued data series, or the data series from the complex-valued Fourier series expansion.

C. USAGE

1. Operational Procedure and Parameters:

This is a CODAP subroutine with a FORTRAN-63 calling sequence CALL COOL (N, X, SIGN). X is a complex array used for the data series and the transform; the number of elements of X is $L=2^N$; SIGN = -1.0 for a direct Fourier transform, and +1.0 for an inverse Fourier transform (but see below for arrangement of data).

For the direct transform: on input the real part

of X contains the data series and the imaginary part of X is zero. On return, the Fourier cosine series expansion is in the real part of X, and the Fourier sine series expansion is in the imaginary part of X. Each contians only $2^{N-1} + 1$ nonredundant points; the cosine expansion is symmetric about point number $2^{N-1} + 1$ and the sine transform is antisymmetric about this point.

For example: N = 3 and data = (0., 1., 0., 0., 0., 0., 0., 0., 0., 0.); Re(X) = (0., 1., 0., 0., 0., 0., 0., 0., 0., 0.); Im(x) = (0., 0., 0., 0., 0., 0., 0., 0., 0.) On imput. On return, Re(X) = (1.000, .7071, 0., -.7071, -1.000, -.7071, 0., .7071); Im(X) = (0., -.7071, -1.000, -.7071, 0., .7071, 1.000, .7071). Point number 1 corresponds to zero frequency; point number 5 corresponds to π .

For inverse transform: the cosine and sine series must be folded over about point number $2^{N-1}+1$ before calling COOL with SIGN = +1.0.

There is a scale factor of 2^{-N} which COOL does <u>not</u> apply. The user can choose to apply the scale factor either to the direct or to the inverse transform, or to apply a factor of $2^{-N/2}$ to both. For example, if COOL were called with the transform example above, the result would be Re(X) = (0., 8., 0., 0., 0., 0., 0.) and Im(X) = (0., 0., 0., 0., 0., 0., 0., 0.).

- 2. Space Required: Approximately 200₁₀ exclusive of X. The largest series that can be transformed in a 32K core machine is 8K.
- 3. Temporary Storage Required: None. Other versions of this program have an auxiliary storage for the cosine table and/or a table of hit-reversed numbers. COOL computes its sines and cosines as it goes, and uses an algorithm due to J. F. Claerbout for calculating the bit-reversed numbers.
- 4. Frintout: None.
- 5. Error Printouts: None.
- 6. Error Stops: None.
- 7. Input and Output Tape Mountings: Not Applicable
- 8. <u>Input and Output Formats</u>: Not Applicable.
- 9. Selective Jumps and Stops: None.
- 10. <u>Timing</u>: Time is proportional to N². Transforming 8192 on the CDC 1604-B requires 25.0 seconds.
- 11. Accuracy: Calling COOL returns the original to about nine decimal places.
- 12. Cautions to User: See Operational Procedure above.
- 13. <u>Configuration</u>: Standard COOP.
- 14. References: J. W. Cooley, 1964 "Harm Harmonic Analysis; Calculation of Complex Fourier Series": IBM Watson Research Center Yorktown Height, New York.

J. W. Cocley and J. W. Tukey, 1965, An Algorithm for the Machine Calculation of Complex Fourier Series:

Math. of Comp., Vol. 19, pp. 297-301.

Writeups of the following SDL programs:

COOLTWO: Does two Fourier transforms at once.

FT3DCOOL: Three-dimensional Fourier transform

D. METHOD

Given a time series X(I), 1, L (where L = 2^N) assumed to be periodic outside the given range, COOL constructs

$$Y(K) = SUM X(J)*W^{JK}$$

$$X = 0, L - 1$$

$$J=0$$

where W = exp $(-2\pi i/L)$ for time-frequency transform, and W = exp $(+2\pi i/L)$ for frequency-time transform. The algorithm is efficient, requiring N'2^N multiplications rather than 2^{2N} .

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. IDENTIFICATION

<u>Title:</u> Multichannel convolution in the frequency domain, for taped data.

COOP Identification: UES G620 COOLCON

Category: G6 Time Series Analysis

Programer: D. W. McCowan

Date: 22 September 1966

B. PUKPOSE

This subroutine convolves data channels on the input subset tape with a multichannel filter stored in core, working entirely in the frequency domain. The result is written in subset format on another tape.

C. USAGE

Operational Procedure: This is a FORTRAN-63 subroutine with calling sequence:

CALL COOLCON (INT, IOT, L, F, X).

2. Parameters:

INT is the number of the input tape unit.

IOT is the number of the output tape unit.

L is the number of points in the filter (see restriction below).

F is the multichannel filter, dimensioned F(N,L) in the calling program, where N is the number of channels on the input subset tape.

X is a working array, dimensioned X(2,IT) is the calling program, where IT is the least power of 2 such that

$$2^{IT} > L + LX$$

where LX is the number of data points in the input channels.

Restriction on length of data and length of filter: LX + L must not be greater than 2^{13} (8K).

- 3. Space Required: Very little in addition to arrays.
- 4. <u>Temporary Storage Required</u>: 2*2^{IT} working space, plus 127₁₀ for the subset tape label.
- 5. Printout: None.
- 6. <u>Error Printouts</u>: If L+LX>2¹³, these numbers are printed with an error message.
- 7. <u>Error Stops</u>: If L+LX>2¹³, the subroutine stops the calling program.
- 8. <u>Input and Output Tape Mountings</u>: See Parameters above.
- 9. <u>Input and Output Formats</u>: Compatible with UES Subset (See Writeup).
- 10. Selective Jump and Stop Settings: None.
- 11. Timing: Dominated by two Fourier transforms using COOL

for each channel to be filtered. The length of transform is $2^{\mbox{\scriptsize IT}}$ (See Writeup of COCL).

- 12. Accuracy: This yields the same numbers, to ten decimal places, which would be computed by convolving the filter and data series in the usual way.
- 13. Cautions to User: None.
- 14. Configuration: Standard COOP.
- 15. References: Writeups of UES G612 COOL, UES Z24 SUBSET, and UES G617 COOLER.

D. METHOD

For each channel to be filtered, the subroutine erases $2^{\mathrm{IT}+1}$ locations of X, and multiplexes the filter and the data channel in X, starting at the beginning. Note that as far as COOL is concerned, X is a complex array with data in the real part and filter in the imaginary part. COOL is called, and the logic of COOLER (q.v.) is used to form the Fourier transform of the filtered channel in X. COOL is called again to get back to the time domain, and the filtered channel is written on the output tape.

The subset label is copied from the input tape to the output tape at the beginning of the subroutine.

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. <u>IDENTIFICATION</u>

<u>Title</u>: Hyper-Rapid Specialized Cooley-Tukey Fourier Transform (direct only)

COOP Identification: G617-COOLER

Category: Fourier Transform

Programer: J. F. Claerbout

Date: 27 July 1966

B. PURPOSE

To compute the Fourier series expansion of a real-valued time series.

C. <u>USAGE</u>

- 1. Operational Procedure: This is a FORTRAN-63 subroutine, with calling sequence CALL COOLER(N,X). This subroutine calls COOL.
- 2. Parameters: On input, X is a real-valued time series containing LX points, where LX = 2^N, N is restricted to be 14 or less. On return, X contains LX+1 complex points of the Fourier transform of the data, with the real and imaginary parts <u>multiplexed together</u> i. e., on return X can be thought of as a complex array, with the cosine transform in the real part and the sine

transform in the imaginary part.

X must be dimensioned at least LX+2 in the calling program. (i.e., LX+1 complex points)

- 3. Space Required: Very little.
- 4. Temporary Storage Required: None.
- 5. Printout: None.
- 6. Error Printouts: None.
- 7. Error Stops: None.
- 8. Input and Output Tape Mountings: Not Applicable.
- 9. Input and Output Formats: None.
- 10. Selective Jumps and Stops: None.
- 11. <u>Timing</u>: Time is proportional to N.2^N; transforming
 16384 points on the CDC 1604-B requires 45.9 seconds.
- 12. Accuracy: About nine decimal places.
- 13. Cautions to User: On return, the real and imaginary parts of the transform are multiplexed together. X must be dimensioned at least LX+2 in the calling program, not LX. This subroutine will not do an inverse transform.
- 14. References: Writeup of UES G612 COOL.

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. <u>IDENTIFICATION</u>

Title: Hilbert transform of periodic data

COOP Identification: UES G619 COOLHLBR

Category: G6 Time Series Analysis

Programer: E. A. Flinn and J. F. Claerbout

Date: 23 September 1966

B. PURPOSE

To compute the Hilbert transform (quadrature function) of a time series. Since COOL is used, the time series is assumed to be periodic outside the range of definition.

C. <u>USUAGE</u>

- 1. Operational Procedure: This is a FORTRAN-63 subroutine, with calling sequence: CALL COOLHLBR(N,X). This subroutine calls COOL.
- 2. Parameters: N is the log (base 2) of the number of data points. X is the data, dimensioned at least 2^N in the calling program, and type complex there.

On input, the real data series must be stored in the real part of X, and the imaginary part must be zero.

On return, the real data series is stored in the real part of scaled up by 2^{N-1} . The Hilbert transform is stored in the imaginary part of X, also scaled up by 2^{N-1} .

- 3. Space Required: Very little in addition to the array for data, which requires 2^{N+1} locations in the calling program.
- 4. Temporary Storage Required: None
- 5. Printout: None
- 6. Error Printouts: None
- 7. Error Stops: None
- 8. Input and Output Tape Mountings: Not Applicable
- 9. Input and Output Formats: Not Applicable
- 10. Selective Jumps and Stops: None
- 11. Timing: Dominated by two calls to COOL
- 12. Accuracy: The data is returned correct to ten decimal places.
- 13. <u>Cautions to User</u>: The data must be arranged as under
 (2) above.

Notice that as far as this subroutine is concerned the data is periodic outside the range of definition. End effects may cause answers which the user does not expect. For example, if the input is a pure sine wave, the user expects the quadrature to be a pure cosine. Using this subroutine, this turns out to be the case only if the data series contains an integral number of cycles.

14. References: Writeup of UES G612 COOL.

D. METHOD

The Hilbert transform of a function has a Fourier transform which is $(-1)^{\frac{1}{2}}$ times the Fourier transform of the function. COOL returns the real and imaginary parts of the Fourier transform of a function calculated from zero to 2π , so that the real part is symmetric about the middle and the imaginary part is antisymmetric.

If the Fourier transform of the function is A+iB, the Fourier transform of the Hilbert transform is -B+iA. All COOLHLBR does is erase the second half of the Fourier transform (the part from π to 2π), half-weight the end points, and call CCoL again to transform back to the time domain.

The scale factor 2^{N-1} comes from the fact that COOL gives the unnormalized transform.

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. <u>IDENTIFICATION</u>

Title: Fourier Transform of Two Data Series Simultaneously

COOP Identification: COOLTWO

Category: G6 Time Series Analysis

Programer: E. A. Flinn

Date: 10 June 1966

B. PURPOSE

To compute the Fourier series expansion, using COOL (q.v.), of two data series simultaneously.

C. <u>USAGE</u>

1. Operational Procedure: This is a FORTRAN-63 subroutine with calling sequence.

CALL COOLTWO (N, X, SIGN, A, B).

2. Parameters:

N is the log (base 2) of the number of elements in X; X contains the two data series, multiplexed in one complex array, so that Re(X) contains one series and Im(X) contains the other.

SIGN = -1.0 . The program has not yet been checked out for inverse transformation;

A is the complex (cosine and sine) transform of the data series stored in the real part of X;

B is the complex Fourier transform of the data series stored in the imaginary part of X;

A and B are both of length 2**(N-1) + 1.

- 3. Space Required: about 70 excluding arrays.
- 4. Temporary Storage Requirements: None
- 5. Printouts: None
- 6. Error Printouts: None
- 7. Error Stops: None
- 8. Input and Output Tape Mountings: None
- 9. Input and Output Formats: Not Applicable
- 10. Selective Jump and Stop Settings: Not Applicable
- 11. <u>Timing</u>: Timing is proportional to N·2^N; transforming 8192 data points on the CDC 1604-B requires 25.0 seconds.
- 12. Accuracy: Same as COOL.
- 13. Cautions to User: This program has not been checked out for inverse transformation. This program does not apply the scale factor ? N, since some users may wish to apply the scale factor to the inverse, rather than the direct transform. The number of data points must be a power of 2.
- 14. Configuration: Standard COOP
- 15. References: Writeup of UES G612 COOL

D. METHOD

The method is due to J. W. Cooley (see Reference 2 in main body of this report.) - C-14 -

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. <u>IDENTIFICATION</u>

<u>Title</u>: Fast convolution of two time series using COOK.

COOP Identification: UES COOLVOLV

Category: Time Series Analysis

Programer: E. A. Flinn and D. W. McCowan

Date: 23 September 1966

B. PURPOSE

To form the convolution of two time series, not by the usual polynomial multiplication algorithm, but by forming the two Fourier transforms (using COOL), multiplying them together, and transforming back to the time domain. This is faster than the usual procedure when

$$LX \cdot LF >> 4 (2N + 1) (LX + LF)$$

where LX is the data series length, LF is the filter impulse response length, and N is the log (base 2) of LX + LF.

C . <u>USUAGE</u>

1. Operational Procedure: This is a FORTMAN-63 subroutine, with calling sequence:

CALL COCLVOLV(LX,X,LF,F)

2. Parameters:

X is the data series to be convolved, dimensioned at least

2^{J+1} in the calling program, where 2^J is the smallest power of two larger than LX + LF.

LX is the length of the data series to be convolved.

F is the filter to be convolved with X.

LF is the length of the filter.

- 3. Space Required: 300₁₀ plus arrays.
- 4. Temporary Locations Required: None beyond filling out X to the first power of two greater the LX + LF.
- 5. Alarms or Special Printout: None
- 6. Error Returns: If LX + LF $\geq 2^{13}$, LF is replaced by -LF and control is returned to the calling program.
- 7. Error Stops: None
- 8. Tape Mountings: None
- 9. Formats: None
- 10. Jump and Stop Settings: None
- 11. <u>Timing</u>: Dominated by two calls to COOL for LX + LF points each time.
- 12. Accuracy: Gives the same results as polynomial multiplication to ten decimal places.
- 13. Cautions: None
- 14. Configuration: Standard COCP
- 15. References: Writeups of COOL, COOLCON, AND COOLER

D. METHOD

The same method is used as used in COOLCON.

SEISMIC DATA LABORATORY ALEXANDRIA, VIRGINIA

DIGITAL COMPUTING SECTION

A. IDENTIFICATION

<u>Title</u>: Two and Three Dimensional Fourier Transform Package

COOP Identification: G615 FT2DCOOL, FT3DCOOL

Category: G6 Time Series Analysis

Programer: D. W. McCowan

Date: 20 April 1966

B. PURPOSE

The subroutines in this package compute two and three dimensional Fourier transforms. Their names are: FT2DCOOL, FT3DCOOL, COOL, MATRA63, and SCALE. As with COOL, the dimensions on the data must be a power of two.

C. USAGE

1. Calling Sequence:

CALL FT2DCOOL (X,N,M, SIGNI)

and

CALL FT3DCOOL (X,N,M,L, SIGNI)

2. Arguments:

X, the complex array in which the data is supplied and in which the Fourier transform is returned. If real data is supplied, it must be put into the real part of X and the imaginary part must be erased.

N,M,L, the dimensions of X. Each of these numbers must be a power of two. The number of complex points in the Fourier transform will be N/2 + 1, M/2 + 1, and L/2 + 1 in each direction.

SIGNI, a switch determining the type of transform to be performed. SIGNI = -1.0 gives a direct transform (time to frequency), and SIGNI = +1.0 gives the inverse.

- 3. Space Required: 500 locations.
- 4. Temporary Storage: None
- 5. Alarms and Printouts: None
- 6. Error Returns: None
- 7. Error Stops: None
- 8. Tape Mountings: None
- 9. Formats: None
- 10. Jumps and Stop Settings: None
- 11. <u>Time Required</u>: Three-dimensional Fourier transforms require

 NM + NL + ML one-dimensional Fourier transforms. Two-dimensional Fourier transforms require N + M one-dimensional

 Fourier transforms. For the timing of one-dimensional Fourier
 transforms, see References.
- 12. Accuracy: Same as COOL
- 13. Cautions to Users: None
- 14. Equipment Configuration: Standard COOP
- 15. References: Writeup of UES G612 COOL 3/30/66

D. METHOD

The direct 2 and 3-dimensional Fourier transforms are defined as:

$$A(j_1, j_2) = \frac{1}{\sqrt{NM}} \sum_{k_1=0}^{N-1} \sum_{k_2=0}^{M-1} x(k_1, k_2) w_1^{-j_1 k_1} w_2^{-j_2 k_2}$$

and

$$A(j_{1},j_{2},j_{3}) = \frac{1}{\sqrt{NML}} \sum_{k_{1}=0}^{N-1} \sum_{k_{2}=0}^{M-1} \sum_{k_{3}=0}^{L-1} x(k_{1},k_{2},k_{3})$$

$$w_1^{-j_1k_1} w_2^{-j_2k_2} w_3^{-j_3k_3}$$

Where
$$W_1 = \exp(2\pi i/N)$$
; $W_2 = \exp(2\pi i/N)$; $W_3 = \exp(2\pi i/L)$

The two-dimensional transform is broken up into N + M one-dimensional transforms and the three-dimensional transform is broken up into L two-dimensional transforms and NM one-dimensional transforms.

DIGITAL COMPUTING SECTION

A. IDENTIFICATION

Title: Spectral Matrix Estimates

COOP Identification: G618 SPECTRUM

Category: Time Series Analysis

Programer: D. W. McCowan

Date: 10 July 1966

B. PURPOSE

This is a package of three FORTRAN-63 subroutines for computing an estimate of the spectral matrix for N channels of data stored on magnetic tape. It uses the hyper-rapid Fourier transform routine COOL, and makes use of two tapes and the disc to cut running time to a minimum. The names of the three routines in the package are: SPECTRUM, DOTEM, and SMOOTH. In addition to these, three more subroutines are assumed to be on the system tape; they are: COOL, SKIPREC, and ERASE. Since all other routines are called internally by SPECTRUM, only the calling sequence for it will be given.

C. USAGE

1. Calling Sequence:

Call SPECTRUM (IT, JT, KT, S, NS, LF, X)

2. Arguments:

- IT, the input subset tape number on which the N channels of data are written. The length of each channel must be exactly a power of two.
- $J\hat{T}$, the number of a scratch tape.
- KT, the number of a scratch tape.
- a triply subscripted FORTRAN-63 complex array used both S, for internal manipulation and to return the computed spectral matrix as a N by N by LF complex array with subscripts varying in that order. Here N is the number of channels read from the input tape label and LF is the smoothed length of each spectral estimate. This array must also be 4*LX+4 locations in length, since it is also used for internal computations. LX is the length of the input data channels read from the input tape label. Remembering that there are two locations used for each complex number, the total dimensions on S in the main program must be 2*N*N*LF or 4*LX+4, whichever is the larger. It is usually convenient to dimension it as complex N by N by L F63 array in order to facilitate L here is a number chosen so that S will be large enough as described above.
- NS, the number of times to apply the hanning smoothing operation to the original estimates.

LF, the returned length of the spectral estimates. This is computed from the formula:

LF = (LX/(2**NS) + 1

LF must not be larger than 129.

- X, an array used for internal manipulation, containing at least 2*LF locations.
- 3. Space Required: 502 locations
- 4. Temporary Locations: None
- 5. Alarms or Special Printout: None
- 6. Error Returns: None
- 7. Error Stops: The subroutines stop if length of data series exceeds 2¹³.
- 8. Tape Mountings: See Arguments
- 9. Input and Output Formats: See Arguments
- 10. Jump Settings: None
- 11. <u>Time Required</u>: A 10-channel, 4096-point, NS = 6 case takes approximately 10 minutes of 1604 time.
- 12. Accuracy: Single precision
- 13. <u>Caution to Users</u>: The subroutine as written requires that the data series should contain a number of points exactly a power of two.
- 14. Equipment Configuration: Standard COOP
- 15. References: Writeup of subroutine 5 G612COOL, 6/1/66

Writeup of program UES Z24 SUBSET

Stockham, T. G., 1966 <u>High Speed Convolution and Correlation</u>, AFIPS Proceedings

D. METHOD

The spectral matrix elements $S_{ij}(k)$ are usually defined as Fourier transforms of correlation functions $R_{ij}(t)$. However, it must be realized that these correlations are transient correlations where the functions are considered to be zero outside the region of interest and 100% lags are taken. They are defined as follows:

$$R_{ij}(t) = \sum_{\tau=0}^{T-1-t} x_i(\tau) x_j(\tau + t)$$

$$R_{ij}^{(-t)} = \sum_{\tau=t}^{T-1} x_i(\tau) x_j(\tau - t) = R_{ji}^{(t)}$$

The spectral matrix element is then

$$S_{ij}(k) = \sum_{t=0}^{T-1} \sum_{\tau=t}^{T-1} x_i(\tau) x_j(\tau - t) w \frac{tk}{2} + \sum_{t=1}^{T-1} \sum_{\tau=0}^{T-1-t} x_i(\tau) x_j(\tau - t) w \frac{tk}{2} + \sum_{t=1}^{T-1-t} x_i(\tau) x_j(\tau - t) w \frac{tk}{2} + \sum_{t=1}^{T-1-t} x_i(\tau) x$$

$$x_{i}(\tau) x_{j}(\tau+t) W \frac{-tk}{2}$$

This can be shown to be equivalent to:

$$S_{ij}(k) = F_{i}^{*}(k) F_{j}(k).$$

where
$$T-1$$

$$F_{i}(k) = \sum_{t=0}^{\infty} x_{i}(t) W^{-\frac{tk}{2}}$$

This is recognized as the Fourier transform of the input data computed over twice its length with zeros filled into the second half. The Cooley-Tukey hyper-rapid Fourier transform routine COOL is used to provide the high speed necessary here.

Each spectral matrix element is originally T + 1 complex points long between DC and the folding frequency. It is then smoothed with a hanning window NS times to its final length of LF points.
